

Your task is to write code to learn how to predict essay scores from the 4th root of the length of the text, and OVIX (lexical diversity). How to write the code is up to you, but at the end you will need to obtain and note down the following information: the two weights (coefficients) corresponding to each of the two predictor variables, as well as the bias value; the values for training loss and validation loss after training, computed as averages on the whole training and validation sets, respectively; the learning rate that you used for training; the number of epochs required for training, that is, the number of times each training example has been used.
